Original Research Article

ABSTRACT
This research was conducted to determine the fungal pathogens responsible for post harvest losses of pineapple sold at Wudil and Yan lemon markets. Two samples of pineapples were purchased twice a week from both Wudil and Yanlemo markets for four months. The samples were investigated for the presence of fungal pathogen using standard microbiological methods. The methods involve mounting small portion of pineapple in the plate containing Potato dextrose agar to isolate the fungi. Three fungal pathogens belonging to Aspergillus species were isolated, and Aspergillus niger had the highest frequency of occurrence of (50%). Followed by A. flavus with (27%). The A. fumigatus had the lowest frequency of occurrence of (23%). The differences between the fungal isolates recorded were significantly different (P<0.05) between the two markets, where higher fungal isolates

*Corresponding author: E-mail: sanimyahya@gmail.com;
were recorded at Yanlemo market 159 (40.6%) and Wudil 38 (9.71%). The study showed that the post harvest losses of pineapple in the two markets are attributed to fungal infection. Therefore, safe guarding the two markets from debris and dumps of rotten fruits and vegetable may assist in reducing fungal inoculums in the two markets.

Keywords: Fungi; post harvest; incidence; Wudil; Yan lemo.

1. INTRODUCTION

The pineapple (Ananas comosus) is a tropical plant with edible multiple fruit consisting of coalesced berries it is the most economically significant plant in the Bromeliaceae family [1,2,3]. Pine apples may be cultivated from a crown cutting of the fruit, possibly flowering in 20–24 months and fruiting in the following six months [4].

Pineapples can be consumed fresh, cooked, juiced, or preserved. They are found in a wide array of cuisines. In addition to consumption, the pineapple leaves are used to produce the textile fibre pina in the Philippines, commonly used as the material for the men's barong Tagalog and women's barot saya formal wear in the country [5]. The fibre is also used as a component for wallpaper and other furnishings [5]. The fruit is a good source of vitamin A, B, C and also calcium, magnesium, potassium and iron [5]. It is also a good source of bromelin, a digestive enzyme. It is consumed fresh or in the form of juice, jam, squash and syrup [5].

In West Africa pineapple is grown in gardens and irrigation schemes. In Nigeria, most pineapple is grown in the southern parts of the country [6,7] and there is no record of any systematic or organized traditional storage method for the fruits. They are usually sold immediately after harvesting. They are packed in baskets, cardboard boxes, or wooden crates ready for transportation to the markets [7].

Like many other fruits pineapple highly perish product, and the quality is affected by post harvest handling, transportation, storage and marketing [8]. This may result in decay and production of microorganism which become activated because of the changing physiological state of the fruits [9]. It is estimated that 20% of all fruits harvested for human consumption are lost through microbial spoilage [8]. Spoilage of fruit usually occurs during storage and transit and also while waiting to be processed [7,10].

Pineapples are subject to a variety of diseases, which include wilt disease, pink disease, bacterial heart rot, anthracnose, fungal heart rot, root rot, black rot, butt rot, fruit let core rot, and yellow spot virus [7,11]. Contamination of pine apples may take place at all stages during pre and post-harvest stages. Cultivation and operation or preparation of fruit is responsible for this contamination [12].

The ripened pineapple fruits are easily affected while the green ones show resistance to infection because they don't meet the nutritional requirements of the fungi [8]. The enzymes potential necessary for invading green fruits is greater for ripe ones and it is temporarily beyond the capability of the fungi [8].

Ayanda et al. [13] identified fungi and bacteria as the major organisms causing deterioration of pineapple and other fruits in Nigeria and this occurs by the secretion of extra cellular cell wall degrading enzymes, this factor influences virulence of pathogens. In another related study [14] shows that in Nigeria, fungi constitute the major limiting factor to the production of perishable fruit. Losses caused by fungal attack vary from 20-30% [15,16]. However, for a successful control of losses due to pathogenic microorganism baseline information is required to know precisely the types of pathogens that are involved which will prepare ground for the control strategies. Therefore, this study is aimed at isolating and identifying fungal pathogens responsible for post harvest losses of pineapple on sale at Wudil and Yan lemo market which will provide baseline information for the development of control strategy.

2. MATERIALS AND METHODS

2.1 Study Site

2.1.1 Wudil market

Is located at Wudil Local Government Area of Kano state. It is one of the largest markets in Kano state. It has no good storage facilities for fruits including pineapples Some marketers store their grains on rusted basins and hardly use chemicals on their grains.
2.1.2 Yan Lemo market

Is located at Tarauni local government area of Kano state and is similar in form and structure to Wudil market above.

2.2 Experimental Procedure

A survey was carried out to provide information on the incidence of fungal species responsible for the loses of pineapple on sale at Wudil and Yan lemo markets within February and March, 2018.

2.3 Sample Collection and Collection Site

Two samples of pineapple were purchased twice a week directly from vegetable sellers each at Wudil and Yan lemo Markets and transported to laboratory at Kano university of science and Technology in polyethylene bags for plating. The methods used in sampling and plating follows the one used by [17].

2.4 Sample Handling

Pineapple obtained from Wudil and Yan lemo markets were surface sterilized by immersion in 3% (v/v) sodium hypochlorite solution for three minute. Then rinsed three times in running tap water and allowed to dry. Portion (2 mm) was cut with sterilized scapel and placed on Potato Dextrose Aga (PDA) plate and incubated at 25-27°C for three days.

2.5 Isolate Count and Subculture

Each week growth of fungal isolate was monitored and the number of isolates that appeared was counted and recorded. Each distinct isolates was sub cultured into fresh PDA.

2.6 Pathogenecity Test

Pathogenicity test was conducted to prove Koch’s postulate. Diseases free pineapple were surface sterilized with 10% (v/v) sodium hypochlorite solution and rinsed three times in running tap water and wiped dry using sterile cloth allowed to dry. A 2 mm diameter cycle was measured on the samples and then streak with fungal hyphae on the circular portion. Controls were inoculated with sterile distilled water. Materials were placed on the laboratory bench, sterilized forceps were used to the removed portion from disease areas on the 4th day after inoculation and placed on freshly prepared PDA plates and incubated at 25-27°C for three days. Fungal growth that appeared was examined.

2.7 Microscopic Examination

Fungal mycelium was placed on a clean glass slide. One drop of cotton blue lactophenol was added and the cover slip placed. The slide was mounted on the microscope and observed at magnification of x 10 and x 40. Morphological characteristics of fungal isolated were determined and identified using method described by Dorothea, et al. (1976). Photographs of Aspergillus species were taken from mounted slide using camera Lucida at biology laboratory Kano University of science and technology, Wudil.

2.8 Statistical Analysis

The data were analyzed statistically using one way analysis of variance (ANOVA) and difference among the means were determined for significance at < 0.05. This was achieved using computer program (SPSS, 16.0).

3. RESULTS

A total of Three hundred and ninety one fungal isolates were counted during the study at both Wudil and Yan lemo market A. niger was the highest occurring species with 197 isolates accounting to 50.31% followed by Aspergillus fumigatus 89 isolates at 22.25%). Aspergillus flavus was third with 65 isolates 16.62%. While the lowest occurring was Rhizopus stolonifer 40 isolates at 10.23% spp (Table 1).

3.1 Variation of the Colony Counted in Wudil and Yan Lemo Market

Higher numbers of fungal species were isolated at Yan lemo market with 159 at 40.66%. While Wudil market recorded 38 at 9.71% species (Table 1). The differences between the colonies counted at Wudil and Yan lemo markets were statistically significant (P< 0.005). During the study period high numbers of fungal species were recorded in the second week 106 at 27.10%. While the least number of fungal species 86 at 21.99% was recorded in the first week (Table 2).

3.2 Pathogenecity Test

The results of the pathogenicity test confirmed all the four criteria outline in Koch postulates for identification of the causative agent of a particular disease [18]. The pathogen where

Key: + = Isolates grow with a similar growth characteristic features to the original diseased samples A

In the present study A. flavus and R. stolonifer were the third and fourth occurring isolates, the occurrence of these pathogens might be related to their ability to produce resistant spores, as reported by [22] and [17] that spores of Aspergillus are more resistant to high temperature. And in conjunction with this, Aspergillus species have been implicated in the spoilage of fruits and vegetables in Nigeria [21,17]. The result obtained in the present study shows that the pineapple fruits were contaminated by multiple pathogen [23,24,25]. [17] reported that temperature and relative humidity of the fungi have a significant effect on the growth of the pathogens and their subsequent relevance to spoilage.

The high colony counts obtained at Yanlemo market could be attributed to the damping of waste and spoiled fruits and vegetables within the markets acting as source of contaminants in addition to discharge of effluent which might have assisted in infecting the two markets. Such discharge from rotten and spoiled fruits could contain some nutrients that might favour the growth of the fungi as against the lower number of colonies isolated at Wudil market [17].

Therefore, It can be concluded that the four fungal species namely Candida albican, A. niger, present in all cases of the disease. The same pathogens were isolated from the diseased host and grown in pure culture. When inoculated into a healthy sample of pineapple fruit the pathogen from the pure culture causes the same disease [19]. The same pathogen was re isolated from the new host and shown to be the same as the originally isolated pathogen (Table 3).

4. DISCUSSION

The quality of perishables is affected by post harvest handling, transportation, storage and marketing. This may result in decay and provide suitable condition for invasion by microorganism which may become activated because of the changing physiological state of the fruits [7].

In the present study A. niger was the most frequently occurring isolate followed by A. fumigatus, this findings were similar to the report of [20] and [21] who studied fungal deterioration of some vegetables in Nigeria and found that losses is attributed to the activities of A. niger, A. fumigatus , Mucor, and Rhizopus stolonifer. The finding also agrees with the work of [9] who isolated, A. niger, A. flavus, Rhizopus, and Mucor from samples of vegetables grown at Nassarawa local government area of Kano state.
A. fumigatus, and A. flavus, are the common post harvest fungi associated with pineapple on sale at the studied markets. The results obtained in this study indicate that Wudil, area is the most suitable for marketing of fresh and healthy fruits. This is because in Wudil area there is total absence of household and industrial effluents in the area surrounding the market this might have accounted for the least isolate count. Yanlemo site is the least suited for marketing of fruits because; effluents from rotten and spoiled fruits are not dumped within and surrounding area of the markets. Rather rotten and spoiled fruits are not dumped within and surrounding area of the markets. Rather rotten and spoiled fruits should be disposed of properly away from the market. Likewise marketing of fruits should be prohibited in any area close to the refused dump of rotten and spoiled fruits. Otherwise, the presence and subsequent spoilage due to these fungi could lead to serious economic loss and possible health hazards during consumption.
